Object Class (nonspatial table)
Conceptual Models

Characterized all features or phenomena as:

- Discrete objects; e.g. wells, roads, rock bodies, etc.
  - *Object-based models*

- Continuous phenomena; e.g. gravity, topography, temperature, snowfall, soil pH, etc.
  - *Field-based models*

ArcGIS Desktop

**Basic**
- ArcView

**Standard**
- ArcEditor

**Advanced**
- ArclInfo

**PRODUCTS (Licensing Levels)**

**DATA SOURCES**
- Files
- Databases
- ArclMS Services
ArcGIS Licensing Levels

- **Basic** – Entry level; make maps, do queries, some spatial analysis, some editing (shapefiles, personal geodatabases) – included with GTK ArcGIS Desktop
- **Standard** – midlevel; advanced editing, multi-user geodatabases; more tools in toolbox
- **Advanced** – full functionality; control of “all aspects of data building, modeling, analysis and map display

*UT D.G.S. licenses*
## ArcGIS Extensions

ESRI Data Models

- **Topologic:**
  - ArcInfo - Coverage
  - ArcInfo “.EOO” – export format for coverage
  - ArcGIS - Geodatabase

- **Non-Topologic:**
  - ArcView (legacy) - Shapefile
Early ESRI Data Models

Spatial Data

- Coverages
  - Developed for workstation Arc/Info ~ 1980
  - Complex structure, proprietary format
  - Attributes in Info tables

Aspatial Data

- Shapefiles
  - Developed for ArcView ~ 1993
  - Simpler structure in public domain
  - Attributes in dBase (.dbf) tables

Geographic coordinates and attributes are stored in separate but linked files.

Slide courtesy of D. Maidment
Data Organization

- **Coverage**
  - Data split between coverage and INFO *folders*
  - Common boundaries between polygons stored once
  - Topology explicitly stored
    - Planar graph maintained

- **Shapefile**
  - Data divided among three or more *files* (.shp, .shx, .dbf, .sbx, .sbn, et al.)
  - Common boundaries between polygons stored twice
  - Topology created on-the-fly
    - Planar graph not required

As in previous lecture
Folder/File Organization

Coverage

- Texas
  - Geology
    - aat.adf
    - arc.adf
    - pat.adf
    - Etc., Etc., Etc.
  - Info
    - arc.dat
    - arc.nit
    - Etc., Etc., Etc.

.Shapefile

- Texas
  - Geology.shp
  - Geology.shx
  - Geology.dbf
  - Geology.prj

.E00

- Texas

*One feature shape (as points OR lines OR polygons) per file = “SHAPEFILE”*

*Many related features (as points AND lines AND polygons) per file = “COVERAGE”*
Data Organization: Coverage in Windows Explorer and ArcCatalog

- **ArcCatalog:**
  - Workspace>Coverage>
  - Feature Class

  ![Arc Catalog](image)
  ![Windows Explorer](image)
  ![Feature Classes](image)
Feature Class

- A collection of geographic objects with the same geometry (point, line, polygon) that share the same attributes.
- A shapefile contains one feature class
- A coverage can contain many feature classes
ArcInfo Coverage

- An integrated, homogeneous set of feature classes (pts., lines, polygons) stored together
- Feature classes unified by a theme, e.g. hydro
  - Spatial (coordinate) data stored in binary files;
  - Attributes and topologic data stored in INFO tables
  - Stored within a “Workspace”
ArcInfo Coverages can contain:

- Primary feature classes:
  - Points, with attributes in PAT (point attribute table)
  - Nodes, with attributes in NAT
  - Arcs, with attributes in AAT
  - Polygons, with interior label points and attributes in PAT
Coverages feature classes can contain:

- **Secondary features:**
  - Tics – registration points for digitized data
  - Annotations – text for map
  - Links – vectors used for adjusting local area to known locations (spatial adjustment)
Coverages can also contain:

- Composite features:
  - Routes – collections of Arcs with measurement system
  - Regions – collections of polygons; adjacent, noncontiguous or overlapping
Shapefile format

- Simpler than coverage; doesn’t store topology
- Feature classes stored independently i.e. points, lines and polys. stored in physically separated files (e.g. no shared INFO table)
- For each type, spatial data stored in a .shp file, attribute data in a .dbf table.
- “Null” or “No Data” numerical values not supported in attribute tables
Shapefiles in ArcCatalog/Explorer

- Folder / Shapefile
- Three or more files per feature class
Shapefile feature class types:

- Point, Multipoint
- Polyline (line with several paths)
- Polygon

Ring – closed, nonintersecting path – simple poly.

Disjointed Rings – multiple polygons define feature

Nested Rings – “Island” or “Atoll” polygons
Shapefile Topology

- Shapefiles don’t store information about adjacency
- Topology is generated on the fly – vertices stored in systematic fashion to deal with containment and adjacency
- Planar enforcement can be broken by editing – not required in structure of shapefile
- But... tools available to maintain planar enforcement when digitizing in heads-up mode
Geodatabase model

- Stores geographic coordinates as one of many attribute in a relational database table; no separation between aspatial and spatial data, as in earlier models
- Uses MS Access for “Personal Geodatabase” (single user)
- Uses Oracle, DB2 or other commercial relational databases for “Enterprise GIS” (many simultaneous users).

Slide courtesy of D. Maidment
Geodatabase Model

- Data structure capable of storing objects with behaviors and relationships, not merely graphical shapes with topology and attributes
- All spatial and attribute data for a feature are stored in a row of a single table
- A Geodatabase is a top-level container for feature classes, coverages, shapefiles, rasters, et al. (more later) – ALL DATA CAN BE IN ONE CONTAINER AND ARE THUS PORTABLE
Geodatabases in ArcCatalog/Windows Explorer

- Geodatabase/Feature Dataset/Feature Class

ArcCatalog

Feature Dataset

Feature Classes

Windows Explorer

ArcCatalog
Feature classes in Geodatabase include:

- Points, Multipoints (groups of points)
- Lines
- Polygons

Plus ....

- Network Junctions (special Nodes)
- Network Edges

For geometric networks

Plus other classes

- Relationship classes
- Object Classes – tabular data without geography
ArcGIS Geodatabase

Workspace

Geodatabase

Feature Dataset

Feature Class

Geometric Network

Relationship Class

Object Class

Slide courtesy of D. Maidment
Geodatabase *Feature Datasets*

- Set of Feature Classes, some with topologies, *that share the same spatial reference*
- All feature classes with topologies must be stored within a Feature Dataset
- Analogous to coverage
Object Class

A collection of nonspatial objects that share the same attributes and are stored in a table (i.e. a simple table)

<table>
<thead>
<tr>
<th>Number</th>
<th>Age_Ma</th>
<th>1_sigma</th>
<th>Rx_Type</th>
<th>Size_kg</th>
</tr>
</thead>
<tbody>
<tr>
<td>123</td>
<td>142</td>
<td>1.5</td>
<td>B_schist</td>
<td>3.4</td>
</tr>
<tr>
<td>124</td>
<td>136</td>
<td>2.0</td>
<td>G_schist</td>
<td>1.3</td>
</tr>
<tr>
<td>125</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Object Class (nonspatial table)
A relationship is an association or link between two objects in a database.

A relationship can exist between spatial objects (features in feature classes), non-spatial objects (objects in object classes), or between spatial and non-spatial objects.
# Relationship class

E.g. relationship between spatial and non-spatial objects

<table>
<thead>
<tr>
<th>Attributes of Condrey_samples_NAD27</th>

Paper Map → Files Of Coordinates

- How are they organized?
  - Data Models, Topology
- How are they stored?
  - Data Organization
- How are coordinates captured?
  - Data Entry, Encoding
Digitizing is:

- Conversion of spatial data to digital form
  - Lines, points or polygons are traced to record coordinates of their locations
- Term conventionally used to denote the process of creating VECTOR data
  - Scanning produces raster data ("bit maps")
  - But software exists to convert raster to vector so can digitize ("vectorize") scanned images
Digitizing is accomplished via:

- Digitizing table or tablet
  - “heads-down” digitizing
  - Large digitizing table
- A mouse, on screen
  - “heads-up” digitizing
  - Aerial photos, other raster or vector sources as base to digitize from
- Software that converts raster to vector
  - Vectorization – batch or interactive modes, e.g. ArcScan extension
Digitizing table

Map

Cursor (Puck)

Control Point

Fixed Digitizing Axes

$X_0$

$Y_0$
Digitizing with a tablet involves:

- Digitize 3 reference points – define position of map w.r.t. digitizing table
- Establishing 4 or more control points - distinctive features at known locations that can be used to register the map to ground coordinates (e.g. UTM, lat./lon.) = “georeferencing”
- Separating features as point, line or polygon and tracing them to separate files (themes)
- (Heads-up digitizing starts with georeferencing)
Digitizing strategies governed by:

- Will data be used for queries and analysis or just visual display?
  - i.e. Topology important or not?
  - “True” G.I.S. functionality or not?
- What are accuracy requirements and how much generalization is permitted?
Spaghetti vs. Topologic models

- **Spaghetti:** Points, lines, polygons and their attributes stored in tables
- **Topological:**
  - Same, but with corresponding tables of information about what’s adjacent or what’s within what
“Building Topology”

- Clean: Edit to ensure planar enforcement
  - Remove sliver polygons & gaps between polygons
  - Correct overshoots, undershoots, leaky polygons
- Build: Add topological attributes to spaghetti
  - Manual
  - Automatic
- Digitizing with topology performed in ArcInfo or with tools in ArcToolbox, ArcMap and ArcCatalog
- Changes to polygons or lines affect topological attributes – Strict rules for editing coverages in ArcMap (topology tools available)
Heads-up digitizing

- Decide whether new file will have planar enforcement
- Create new point, line or polygon feature class(es) in ArcCatalog
- Edit feature class(es) to add features and attributes
- Stop editing
- Save edits as part of new feature class
